

8. Windows

Installed by creating the virtual disk drive and then allocating resources. then created a virtual dvd/cd drive and put the win 11 iso on it, then started the vm from the cd/dvd when booting up.

install guestadditions from the cd drive from the windows explorer of vm

creating snapshots and restoring machine states with them.

basic windows navigation and settings overview

local accounts are specific to a computer

domain accounts have a server called domain controller

details for accounts will be administered from the DC, and not stored on the local computers

local administrator vs standard user: full access vs restricted privileges

making a user, adding them to a group, removing from the group

reset the password for the user, delete, rename the user account

Ticket interrupt:

make a user named Richard and then add them to the administrators group

installing chrome and uninstalling it,

while installing or uninstalling it on a standard user, the password for the admin is required.

file and folder permissions:

authenticated users includes admin and the local user, deny permissions override the allow permissions.

you cannot delete the authenticated users group as the folder inherits the default permissions of the C: drive as it is the root directory of the folder, which happens to be the parent. the folders will always inherit the permissions of the parent in windows.

then go to advanced to change the inheritance from the permission of the C: drive.

disable all inheritance, remove the admin too.

then go to edit on the security tab and then press add button to add the admin account as the user to have some privileges.

then give full control to the admin and save it by pressing the apply button.

after that the standard local user won't have access to that folder or file.

check for updates, and then download and install the updates to have the patches for the latest security threats.

Knowledge Base article can be looked up from the KB00XXXXXX number to find what the cumulative update has. can preview on a different machine so the legacy systems dont dysfunction, sometimes with win updates it happens.

scheduling updates, uninstalling updates

open event viewer to see the critical and error messages. we can take a look at the windows logs from different time ranges by clicking the filter current log button on the right hand side Actions panel.

sort the logs by time or level.

you can subscribe to the remote machines to get their logs too.

if user says they are facing some kind of problem with an application, we can see the logs for errors.

drivers let OS communicate with the hardwares

most of the times when a new device is connected, the OS itself loads the drivers.

sometimes you have to install the drivers.

go to the manufaturers' website to download the drivers and then install them. locate the driver on the computer after pressing search for driver locally from the update driver panel, and then install it.

connecting to a printer that is on the network. click devices and printers in the device manager and then open devices and printers window. then click add a device. then it will search for the devices, select the device and then add it.

properties of that added device shows the location and the ip address too.

device manager basically shows what devices are connected and which of them are properly loaded with the drivers' installed and which of them are not which just show up and require a driver.

task manager can be opened by right clicking on the task bar or using ctrl + alt + del.

on a vm, use the input button from the nav bar at the bottom that hides itself, hover at the bottom and then go to input and press Instert Ctrl alt del to get the same options and select the task manager.

task manager helps us too see what processes are using how much power, memory, disk, gpu or network. so it will help in troubleshooting by sorting them in the way we want.

to end that task or kill the process, task manager is useful. usually when a program is crashing or not responding.

we can see what processes of which user are eating up the resources.

windows services run in the background and they dont have any user interface.

go to the start menu and look for services or go to the task manager and then services and then click on open services.

take a look at what the service is doing before stopping it or disabling it even if it is using a lot of resources as it might be important service of the system.

changed the windows wallpaper from the registry editor, (admin user)>control panel>desktop>wallpaper

be cautious when editing the registry values or adding or deleting any other value because some registry files can be integral for the OS.

cmd:

dir -> lists the directories in that path

cls -> clears the screen

cd -> changes the directory to that path/folder

press tab to auto complete the names of the files/folders or the paths

cd .. -> goes back one directory

cd C:\Users\ganesh -> changes the path to

ganesh user

but the access is denied

because the cmd has to be run as the administrator while opening it.

.exe files can be ran by just typing there name as the prompt when the working directory has that .exe file, if not, the path has also to be specified. ex: Downloads\setup.exe

ipconfig -> networking information

ipconfig /? -> opens the help page for that command.

any command name with /? will open that command's help page.

/all -> after a command gives more detail.

ex: ipconfig /all

ping -> only brings up ping command's help page

because it is not being used properly

ping /? -> also brings the help page

ping 8.8.8.8 -> sends ping requests to 8.8.8.8

and waits for reply and

calculates the time passed.

ping -n 1000 8.8.8.8 -> sends 1000 echos
(-n [count])

Ctrl + C halts the command from completing

task scheduler:

open from start menu.

see the tasks that ran, or are running.

create a task and schedule it to run.

ex: disk cleanup

cleanmgr -> on cmd will open disk cleanup

put the name of the task, trigger, and action.
